Build a Classification Table

Description

Creates a wide-format taxonomic classification table from a list of taxon classification outputs.

Usage

```
build_classification_table(list_taxa_classifications)
```

Arguments

`list_taxa_classifications`	A list of data frames. Each data frame is expected to contain 'sel_name' and a nested 'classification' column. The nested 'classification' table should contain 'rank' and 'name' columns.

Details

The function removes 'NULL' list elements, binds rows across all entries, unnests 'classification', filters to standard taxonomic ranks ('kingdom', 'phylum', 'class', 'order', 'family', 'genus', 'species'), removes duplicate 'sel_name'-'rank'-'name' combinations, and pivots to wide format. 'values_fn = dplyr::first' is used as a defensive guard if multiple names are present for the same taxon and rank.

Value

A data frame in wide format with up to eight columns ('sel_name' plus one column per taxonomic rank) and one row per 'sel_name'. Ranks not available for a given taxon are 'NA'.
