Compute Predictor-Inclusive Variance Components

Description

Computes the full variance contribution associated with each predictor domain without dividing shared fractions among domains.

Usage

```
compute_predictor_inclusive_variance_components(data_source)
```

Arguments

`data_source`	A non-empty data frame with columns 'age', 'component', and 'R2_Nagelkerke'. Missing fraction labels are treated as zero, and negative R-squared values are clamped to zero.

Details

Each shared fraction contributes in full to every predictor domain that it contains. Percentages use the sum of the seven clamped variance fractions as their denominator, so percentages across domains may exceed 100 percent.

Value

A tibble with three rows per age and columns 'age', 'component', 'R2_Nagelkerke_predictor_inclusive', and 'R2_Nagelkerke_predictor_inclusive_percentage'.
