Compute Shapley-Allocated Variance Components

Description

Converts a long-format variance-partitioning table into per-age percentages for Abiotic, Associations, and Spatial components using equal-split Shapley allocation.

Usage

```
compute_shapley_variance_components(data_source)
```

Arguments

`data_source`	A non-empty data frame with columns 'age', 'component', and 'R2_Nagelkerke'. Missing intersection labels are treated as zero, and negative R^2 values are clamped to zero.

Details

Each two-way intersection is split equally between its two components, and the three-way intersection is split equally among all three components. The adjusted values therefore sum to the total of all seven clamped fractions.

Value

A tibble with exactly three rows per age and columns 'age', 'component', 'R2_Nagelkerke_adjusted', and 'R2_Nagelkerke_percentage'.
