Compute sjSDM Predictive Loss Shares

Description

Normalizes positive repeat-level log-loss effects across removed components.

Usage

```
compute_sjsdm_decomposition_loss_shares(data_repeat_effects = NULL)
```

Arguments

`data_repeat_effects`	Repeat table returned by [summarise_sjsdm_decomposition_effects()].

Details

Negative effects are retained in 'mean_delta_full_advantage' but contribute zero to normalized shares. Shares are undefined when no component has a positive effect. These are relative predictive-loss shares, not ecological variance fractions, and component overlap prevents causal interpretation.

Value

A named list containing repeat-level shares and descriptive share summaries.

Examples

```
## Not run:

compute_sjsdm_decomposition_loss_shares(data_repeat_effects)

## End(Not run)
```
