Interpolate Community Dataset from Shared Inputs

Description

Slices shared paleo preprocessing inputs to one dataset and interpolates it.

Usage

```
interpolate_community_dataset_from_shared_inputs(
  list_interpolation_index = NULL,
  data_community = NULL,
  data_age_uncertainty = NULL,
  n_cores = 1L,
  ...
)
```

Arguments

`list_interpolation_index`	A metadata object produced by [build_community_interpolation_index()].
`data_community`	Community data or a descriptor from [build_shared_interpolation_data()].
`data_age_uncertainty`	Age-uncertainty data or a shared descriptor.
`n_cores`	Number of cores passed to [interpolate_paleo_community_with_age_uncertainty()]. Dynamic target branches should use '1L'.
`...`	Additional arguments passed to [interpolate_paleo_community_with_age_uncertainty()].

Details

Inclusive row ranges keep branch payloads constant in size and avoid full-table logical masks inside concurrent workers. During the one-time migration from persisted live 'mori' handles, a prebuild may reuse an existing branch object after separately confirming durable inputs are current.

Value

A data frame with columns 'dataset_name', 'taxon', 'age', and 'value'.
