Aggregate Trait Values to Single Value per Group

Description

Aggregates a long-format trait data frame to one row per group (by default per taxon x trait combination) using a specified summary function. Intended to be applied after outlier removal.

Usage

```
aggregate_trait_values(
  data_trait_values,
  trait_value_column = "trait_value",
  group_columns = c("taxon_name", "trait_domain_name"),
  aggregation_method = c("median", "mean")
)
```

Arguments

`data_trait_values`	A data frame in long format with at least the columns specified by 'trait_value_column' and 'group_columns'.
`trait_value_column`	A character string naming the numeric column containing trait values. Default: '"trait_value"'.
`group_columns`	A character vector of column names used to define groups for aggregation. Default: 'c("taxon_name", "trait_domain_name")'.
`aggregation_method`	A character string specifying the aggregation function. One of '"median"' (default) or '"mean"'. Matched with 'match.arg()'.

Details

The 'aggregation_method' argument is processed via 'match.arg()', so partial matching is supported (e.g. '"med"' resolves to '"median"').

Value

A data frame with one row per unique combination of 'group_columns' and a new column 'trait_value_aggregated' containing the aggregated value.
