Evaluate sjSDM Cross-Validated Predictions

Description

Pools selected-candidate out-of-fold predictions within each repeat and taxon, then calculates taxon and community predictive metrics.

Usage

```
evaluate_sjsdm_cross_validated_predictions(

  data_predictions = NULL,

  epsilon = 1e-06

)
```

Arguments

`data_predictions`	Long selected-candidate prediction table returned in the data-prediction element of [run_sjsdm_selected_candidate_folds()].
`epsilon`	Probability clipping tolerance passed to [evaluate_binary_log_loss()]. Defaults to 1e-6.

Details

Folds are pooled before metrics are calculated. Any non-ok prediction row makes all metrics for that repeat and taxon incomplete. One-class pooled responses retain the metric-specific undefined statuses from the binary evaluators, while binary log loss remains evaluable.

Value

Named list containing data_taxon_metrics and data_community_summary. Taxon metrics have one row per repeat, taxon, and metric. Community summaries contain the mean finite estimate across evaluable taxa for each repeat and metric.

Examples

```
## Not run:

evaluate_sjsdm_cross_validated_predictions(

  data_predictions = data_predictions

)
```

```
## End(Not run)
```
