Extract Community Taxa

Description

Extracts unique taxon names from in-memory long community data.

Usage

```
extract_community_taxa(data_community = NULL)
```

Arguments

`data_community`	A data frame containing a 'taxon' column.

Details

Taxa retain their first-seen order. An empty community aborts because downstream classification and model fitting require at least one taxon.

Value

A character vector of unique taxon names present in the data.

Examples

```
data_community <-
  tibble::tibble(
    taxon = base::c("Pinus", "Betula", "Pinus")
  )

extract_community_taxa(data_community = data_community)
```
