Extract Data from VegVault

Description

Extracts data from a pre-built vaultkeepr query plan by adding abiotic data, filtering by variable name, adding taxa, and collecting the results into a data frame.

Usage

```
extract_data_from_vegvault(plan, sel_abiotic_var_name = NULL)
```

Arguments

`plan`	A vaultkeepr plan object, typically created by 'build_vegvault_plan()'.
`sel_abiotic_var_name`	A non-empty character vector specifying the abiotic variable names to select (e.g. '"bio1"').

Details

The function extends the supplied plan with the following steps: 'vaultkeepr::get_abiotic_data()' -> 'select_abiotic_var_by_name()' -> 'get_taxa()' -> 'extract_data()'

Input validation and plan construction (geographic/temporal filters, dataset type selection) are handled by 'build_vegvault_plan()'.

Value

A data frame containing the extracted data.
