Load Project Functions

Description

Validates and deterministically loads the active project function tree.

Usage

```
load_project_functions(
  path_function_root,
  environment_target,
  vec_excluded_directory_names = base::character()
)
```

Arguments

`path_function_root`	A single existing directory containing project function files.
`environment_target`	The environment into which validated functions are loaded.
`vec_excluded_directory_names`	Character vector of exact directory names to exclude with all descendants.

Details

Validation occurs before any function is loaded. Each active file must contain exactly one top-level function declaration and no other top-level expressions. Function names must match file basenames; a single leading dot is allowed for an internal function. Duplicate symbols and case-insensitive duplicate basenames are rejected.

Value

A data frame describing the validated functions in source order.

Examples

```
## Not run:
load_project_functions(
  path_function_root = here::here("R/Functions"),
```

```
  environment_target = base::globalenv()
)

## End(Not run)
```
