Prepare Community Proportions

Description

Prepares community pollen-count data as proportions, normalising each sample by its total pollen count.

Usage

```
prepare_community_proportions(data_community = NULL)
```

Arguments

`data_community`	A data frame with columns 'dataset_name', 'sample_name', 'taxon', 'age', and 'pollen_count'. Must contain a 'pollen_count' column with raw pollen counts.

Details

Summarises per-sample totals using [summarise_pollen_counts_by_sample()] and computes proportions with [compute_pollen_proportions()]. The result is suitable for passing to [interpolate_paleo_community_with_age_uncertainty()].

Value

A data frame with the same structure as the input, but with 'pollen_count' replaced by 'value' (pollen counts divided by sample-level total). The 'pollen_count' and 'pollen_sum' columns are dropped.
