Select non-collinear predictors from abiotic data

Description

Filters a data frame of abiotic variables, retaining only predictors identified as non-collinear by a collinearity analysis. The selection is taken from the 'selection' element nested inside 'result' in a 'collinear_output' object (as returned by 'compute_predictor_collinearity()').

Usage

```
select_non_collinear_predictors(data_source = NULL, res_collinearity = NULL)
```

Arguments

`data_source`	A data frame containing abiotic variables. Must include a column named 'abiotic_variable_name' whose values are matched against the selected predictors.
`res_collinearity`	A 'collinear_output' object (as returned by 'compute_predictor_collinearity()'). Its 'result' element must contain a non-empty character vector named 'selection'.

Details

Input validation is performed with 'assertthat'. The function requires that the filtering produces at least one row; if no predictor names match, an error is raised suggesting the user check the collinearity results.

Value

A filtered data frame (same structure as 'data_source') containing only rows whose 'abiotic_variable_name' is in the set of selected non-collinear predictors.
